AB The lubricant for powder metallurgy contains a polyhydroxycarboxamide having a formula of R1CONR2R3, where R1 is C2-10 alkyl with ≥2 hydroxy groups, R2 is C8-30 hydrocarbon group, and R3 is H or C1-30 hydrocarbon group. The lubricant improves fluidity and lubricity in any pretreatment processes for sintering.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A manufacturing process using microwave for thermal debinding according to the invention is mainly applied in the manufacture of powder metallurgy. Wherein, metal powder is mixed with polymer materials such as adhesives, fillers, or lubricants, and a green body is formed by molding, forging, extrusion, injection, or scraping. The green body to be debinded is placed in a microwave environment in an exposed manner or covered with ZrO2 or Al2O3 powder, and power and work time of microwave are set for rapidly heating and debinding the body. This manufacturing process is capable of accelerating manufacturing procedure, economizing production cost, reducing defects, quickly drying and rapidly removing polymer materials. The metal powder is made of a pure metal from or an alloy of iron, titanium, copper, magnesium, nickel, chromium, and manganese. The polymer materials are any from acrylic,

Et cellulose, hydroxypropyl cellulose, polypropylene cellulose, polypropylene, polyacetal polymer, ethylenevinyl acetate, atactic polypropylene, sterene-butadiene copolymer, Me cellulose, polyethylene, oxidized polyethylene, cellulose acetate, nylon, polystyrene, polybutylene, polysulfone, paraffin wax, mineral oil, vegetable oil, fatty acid, fatty alc., fatty ester, hydrocarbon wax, epoxy, polyphenylene, phenol, stearic acid, ester wax, oleic acid, di-Et phthalate, and formaldehyde.

AB The powder mixture comprises Fe based powder and 0.1-1.20 weight% spherical free-standing lubricant powder containing 0.02-5.0 weight% antistatic agents. The mixture may also contain alloying powder and/or powders for improving machinability. Also claimed is the powder mixture comprising Fe-based powder having coatings of the alloying powder and/or machinability-improving powders bonded with binders. The mixts. show excellent flowability and mold filling properties and are suitable for use in powder metallurgy processes.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The manufacturing technique for powder metallurgy of the invention includes the steps of: mixing ceramic powder with binders, fillings or lubricants for casting a body; forming a microwave-absorbent body using molding, extrusion, forging, injection or doctor blade; placing the body into a microwave oven for heating and debinding; placing the half-finished product after debinding in a sintering oven for sintering the debinded half-finished product; and finally obtaining a finished product after sintering and temperature lowering. This leads to an accelerated procedure for the manufacturing of powder metallurgy products.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The invention relates to improved metallurgical powder (e.g., Ancorsteel 1000B) compns. that incorporate solid lubricants, methods for preparing and using the same, and methods of making compacted parts. Ejection properties,

such as stripping pressure and sliding pressure, of compacted parts can be improved by using the solid lubricants. The solid lubricants contain functionalized polyalkylene lubricants have the formula: R1-Q-R2 where Q is a linear or branched, polyalkylene containing from 10 to 200 carbon atoms, and R1 and R2 are each independently a hydroxyl group, a carboxylic acid group or a metal salt thereof, an amine group, a mono- or di-C1 to C25 alkyl substituted amine group, or an alkylene oxide group having the formula: $-(CH_2)_qO)_nH$ where q is from 1 to 7, n is from 1 to 100. The functionalized polyalkylene lubricant is in the form of a powder having a particle size of 2-200 μm . The polyalkylene comprises polyethylene, polypropylene, polybutylene, polypentylene or combinations thereof. The solid lubricant composition, of at least one addnl. lubricant comprising amines, amides, or polyamides, metal salts of polyamides, fatty acids or fatty alcs., metal salts of fatty acids, or combinations thereof (e.g., 30 weight% of stearic acid, ethylene bis-stearamide, and 40 weight% of polyethylene alc. Unilin 700).

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A manufacturing method for high-d. Fe-based powder compacts is disclosed. The temperature of the die is adjusted at ordinary temperature or at a predetd. temperature by preheating. A lubricant for die lubrication prepared by mixing of ≥ 2 different lubricants having m.ps. higher than a predetd. temperature of the compaction pressure is sprayed at the upper part of the die and is introduced into the die and adhered by electrification to the surface of the die. The resulting die is filled with an Fe-based mixed powder including a lubricant and molding is performed at ordinary temperature or at a temperature raised by heating. The ≥ 2 different lubricants having m.ps. higher than the predetd. temperature of the compaction pressure are preferably ≥ 2 materials selected from ≥ 1 of the following groups: metallic soaps, amide-based waxes, polyamides, polyethylenes, polypropylenes, polymers comprised of acrylic acid esters, polymers having methacrylic acid ester, plastics including fluorine and lubricants having layered crystal structures.

AB The composition contains a metal powder and a lubricant mixture comprising boric acid and 21 other powder metallurgy lubricants, where the amount of lubricant mixture is 0.1-5 weight%. Preferably, the metal powder is a Fe-based powder containing graphite and Cu as additives; and the other powder metallurgy lubricant is Zn stearate, Li stearate, Li 12-hydroxy stearate, ethylene-bisstearamide, or stearic acid. The sintered metal part is manufactured by: compacting the powder mixture with lubricant mixture in a mold, de-molding, heating to remove the lubricant, and sintering.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB An Fe base powder mixture having high flowability at room temperature and good moldability contains an Fe base powder, a lubricant and alloying powder. At least one of the components is coated with ≥ 1 surface-treating agent selected from the group consisting of organoalkoxysilanes, organosilazanes, titanate coupling agents and F-containing coupling agents. The iron base powder mixture is press-molded at a temperature higher than the lowest m.p. but lower than the highest m.p. of the lubricants contained in the mixture

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The metallurgical powder is a mixture of an Fe-base powder, an alloying powder, lubricant, and surface treating agents. The surface treating agents are selected from alkanoalcoxysilane, alkanol-siloxane, silicone oil, titanate series coupling agents, fluoro series coupling agents, and mineral oil. The lubricant is selected from fatty acid amide and/or metal soap, graphite, MoS2, etc.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The Fe-based sintering mixts. contain minor alloying powders (especially graphite at 0.25-5%), ≤15% (especially 0.1-2%) heat-resistant polyamide as a compaction lubricant, and a minor amount (especially 0.005-3%) of organic

binder. The polyamide lubricant is reaction product of C6-12 linear dicarboxylic acid 10-30, C10-22 monocarboxylic acid 10-30, and (CH₂)₂-6(NH₂)₂ diamine 40-80%. The organic binder is selected from cellulose ester resins, hydroxy alkylcellulose resins with C1-4 alkyl moiety, and/or thermoplastic phenolic resins. The polyamide lubricant of ethylene bis-stearamide type (m.p. 200-300°) is suitable for pressing at 149° or 204° of the preforms based on Distaloy 4800A steel powder with graphite powder 0.6, lubricant 0.6, and organic binders 0.15%. The resulting preform d. was .apprx.7.3 g/cm³, and the sintered d. was similar, vs. .apprx.7.13 g/cm³ when pressed at room temperature and .apprx.7.14 after sintering.

AB The invention is characterized in the Fe base powder mixture that is comprised of alloyed steel powder (Ni: 0.5-3 and Mo 0.7-4%), a layer of Ni powder (0.5-5%), Cu powder (0.5-3%), and graphite (0.2-10%) on the surface of the steel

powder, and lubricant (0.05-0.6%). The lubricant is a powder with a size of 10-200 μm that is aggregated from the finer powder with $\geq 20\%$ thereof having a grain size of 0.1-80 μm . The Fe base powder mixture is suitable for high strength P/M products obtained by sintering at low temperature and eliminating after-sintering heat treatment.

- AB The invention concerns powder compns. consisting of elec. insulated particles of a soft magnetic material of an Fe or Fe-based powder and 0.1-2% by weight of a lubricant selected from the group consisting of fatty acid amides having 14-22 C atoms. Optionally a thermoplastic binder such as polyphenylene sulfide may be included in the composition. The invention also concerns a method for the preparation of soft magnetic composite components.

AB Rusting of metal powder is prevented by formation of an oxidation resistant B- and Na-based glass coating by treatment of the powder in an aqueous solution containing inorg. compds. of B and Na, dehydration, and drying. Preferably, the solution also contains organic amino compds. for simultaneous deposition of amino-containing organic compds. on the powder surface. The said aqueous solution, preferably containing 1-20, 000 ppm B and 1-10, 000 ppm Na, is also claimed as a rust-preventive agent. The process is suitable for treatment of metal powder used for powder metallurgy, injection molding, etc.

- AB Near-net-shape soft magnetic components can be produced from iron powder lubricant compns. using powder metallurgy techniques. The resulting components have isotropic magnetic and thermal properties and may be shaped into complex geometry using conventional compaction techniques. A noncoated ferromagnetic powder is mixed with a lubricant and compacted. After compaction, the components are thermally treated at a moderate temperature to burn out the lubricant, relieve the stresses induced during pressing and reduce the hysteresis losses. Depending on the application, the properties of the material may be tailored by varying the content and type of the lubricant and the thermal treatment conditions.

AB A mixture of Fe based alloy powder, graphite, and an organic binder is heated to a temperature equal or above the m.p. of the binder for powder coating of Fe alloy powder with graphite and then mixed with 0.05-0.6 weight% secondary particles (size 10-200 μm) consisting of lubricant primary particles (size 0.1-80 μm) with application of shear force of not breaking the secondary particles. Thus manufactured mixture with >20 weight% of the free lubricant being secondary particles is also claimed. The mixture may also contain other alloy powder and/or powder for improvement of machinability. Compacts having high d. can be manufactured at standard temperature under easy release from the mold.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Compacted metallurgical powder lubricating compns. are composed of (1) a metal-based powder ≥ 80 , (2) a solid lubricant consisting of a functionalized oligomeric polyolefin-type (C8-50) lubricant 0.01-5, and (3) an addnl. lubricant ≥ 10 weight%, selected from amines, amides, polyamides, metal salts of polyamides, C10-25-fatty acids or fatty alcs., and the corresponding metal salts. Component (2) has general structures Q1(R1)x, Q1-(R1-Q2)n-R2, Q1-(R1-Q2)n-R2-Q3, and R1-Q1-(R2-Q2)-R3, in which Q1, Q2, and Q3 are linear or branched C8-1000-polyalkylenes; R1, R2, and R3 are selected from phosphate, phosphite, hypophosphate, hypophosphite, polyphosphate, thiophosphate, dithiophosphate, thiocarbamate, dithiocarbamate, borate, thiosulfate, sulfate, or sulfonate groups; n = 0-10, and x = 1-30.

AB The chemical surrounding the pyrolysis of N,N'-ethylenebisstearamide (EBS) compacted with iron powder is described for the first time. Heat treatment is carried out in a 5 vol pct hydrogen atmospheric (balance nitrogen) over the 100 °C to 850 °C range. The exhaust from the furnace is monitored by Fourier transform IR and dispersive UV absorption spectroscopy; condensable materials are analyzed by gas chromatog./mass spectrometry (GC/MS). A wide range of analytes emitted from the preceding process were characterized. The aliphatic CH stretch in the 3000 to 2700 cm⁻¹ range and the asym. CO stretch in gaseous CO₂ at 2350 cm⁻¹ are excellent indicators of the extent of delubrication. A bimodal CO emission phase is observed in the temperature window between delubrication and sintering. Three major large mol. reaction products, along with five minor compds., are identified by GC/MS. A preliminary reaction mechanism is inferred based on product anal. and known organic chemical. It appears that hydrolysis of EBS competes with γ-H abstraction yielding an N-vinyl amide and stearamide, which undergoes further reaction. Hydrolysis affords stearic acid, which decarboxylates to heptadecane, and 2-heptadecyl-4,5-dihydroimidazole via ring closure of the corresponding amino-amide.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The Fe-based powder mixts. for sintering contain: (a) atomized Fe-alloy powder, and/or sponge-Fe powder; (b) lubricant based on glyceryl stearate at nominally 0.1-2.0% by weight; and (c) optional graphite and metal-alloying powders. The lubricant mixts. optionally contain 5-95% fatty acids and/or stearate salts. The resulting Fe-based powder mixts. are suitable for pressing of preforms at 400-800 MPa with increased green d. and decreased ejection energy, compared with the conventional lubricant based on ethylene bis- stearamide.

OTHER SOURCE(S): MARPAT 140:18732

AB The water-atomized stainless steel powder containing 10-30% Cr is premixed with 0.8-2.0% lubricant for warm compaction in a die at .apprx.110°. The preforms are typically sintered at 1250-1325°, especially for 15-90 min in a non-oxidizing atmospheric. The lubricant mixture contains waxy base or amide oligomer with ≤0.4% of O2-affinity compound (especially Li stearate), minor fatty acid at 0.005-0.5%, and flow promoter (especially colloidal SiO2) at 0.005-2%. The typical lubricant mixture contains amide oligomer 1.0, Li stearate 0.2, stearic acid 0.05, and colloidal SiO2 0.1%. The 410-grade stainless steel powder with the lubricant was compacted at 600 MPa to the green d. of 6.83 g/cm3, and sintered in H2 for 45 min at 1250° to the d. of 7.22 g/cm3.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The powder-metallurgical mixts. for pressing of preforms with decreased sliding and ejection pressure contain: (a) $\geq 80\%$ of metal and/or alloy powders; and (b) 0.01-5% of lubricant powder based on polyalkylene block copolymer with linear or branched C5-500 chains. The lubricant powders contain polyalkylene-polyalkylene oxide block copolymer having the A-B or A-B-A structure, and can be used with optional addition of other lubricants. The typical lubricant is prepared from polyethylene block copolymer with polyethylene oxide, mixed with 30% of stearic acid for 6 h at 175°, atomized for powder manufacture, and cooled. The lubricant powder was suitable for die pressing of Fe-powder mixture at 50 tons/in.2, and sintering the preforms for 30 min in dissociated NH3 atmospheric at 1120°.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB A powder metal blend for a powder metal part, especially a valve guide for an internal combustion engine suited for operation where there is little or no engine oil lubricant at the valve stem and valve guide interface. The powder metal blend contains Cu 2-10, solid lubricant 0.5-5.0, Gra 1-3, bronze 1-8, CuP 0.2-1.5, and/or FeP 0.2-1.5, fugitive lubricant 0.3-1.0, with the balance a low alloy steel powder containing Mn 0.3-1.0%.

AB The metal powder mixts. containing $\leq 0.3\%$ lubricant are pressed in a die at nominally 10-70 tons/in.2, and the resulting green preforms are sintered by induction heating with optional hot forming. The process is suitable for sintering of Fe-powder blends containing graphite 0-3, Ni 0-12, Mo 0-3, Cu 0-10, Mn 0-2, and Cr 0-20%, especially by induction heating the green preforms to 1900-2500° F. The sintered articles are optionally finished by hot pressing at 20-90 tons/in.2 and 200-800° F for densification. The process is suitable for manufacture of sintered steel gears, bushings, and similar machinery parts.

- AB The improved lubricants for use in die pressing of metal-powder preforms for sintering are added as powders, but are liquefied under pressure for lubrication of die walls. The lubricants are added at nominally 0.10-0.50%, and contain fatty acids, guanidine derivs. (especially guanidine stearate), and optionally amide wax and/or petroleum wax. The typical lubricant mixture finished by cryogenic milling contains lauric acid 10, tech. stearic acid 10, com. wax (Acrawax C) 50, guanidine stearate 13.5, and guanidine Et hexanate 16.5%, and is manufactured as powder of 10-25 μ m size. The lubricant powder was added at 0.20% to stainless steel powder 409CS for pressing at 30-48 tons/in.2 followed by sintering for 30 min at 2450° F in H2-30% N2 atmospheric. The resulting green d. and sintered d. were comparable to those from the 409CS powder with 0.75% Acrawax C as conventional lubricant.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

OTHER SOURCE(S): MARPAT 137:327245

- AB A metalworking powdered lubricant for warm compaction of metal (iron-based) powders contains at least one oligomeric amide, a fatty acid, and, optionally one or more additives (e.g., binders, flow enhancers, processing aids, and hard phases). The oligomeric amide is described by general formula D-Cma-B-A-B-Cmb-D (I), in which D = H, -COR, -CNHR (R = C2-21-aliphatic or aromatic); C = -NH-(CH2)n-CO-; B = -NH- or -CO-; A = C4-16-alkylene that can include up to 4 oxygen (-O-) atoms; ma, mb = 1-10; n = 5-11. Preferred lubricants are di(amide-terminated) oligomeric polyamides, I (D = RC(:O)- (R = C16-20-aliphatic); C = -NH-(CH2)n-C(:O)- (n = 5 or 11); B = -NH-; A = C6-14-alkylene, with up to 3 oxygen (-O-) atoms; ma and mb = 2-5). Suitable fatty acids are oleic acid, stearic acid, and palmitic acid.

OTHER SOURCE(S): MARPAT 137:327244

AB A metalworking powdered lubricant for warm compaction of metal (iron-based) powders is described by general formula D-Cma-B-A-B-Cmb-D (I), in which D = H, -COR, -CNHR (R = C2-21-aliphatic or aromatic); C = -NH-(CH2)n-CO-; B = -NH- or -CO-; A = C4-16-alkylene that can include up to 4 oxygen (-O-) atoms; ma, mb = 1-10; n = 5-11. Preferred lubricants are di(amide-terminated) oligomeric polyamides of formula I (D = RC(:O)- (R = C16-20-aliphatic); C = -NH-(CH2)n-

C(:O)- (n = 5 or 11); B = -NH-; A = C6-14-alkylene, with up to 3 oxygen (-O-) atoms; ma and mb = 2-5). Specific lubricants are: CH₃(CH₂)₁₆C(:O)-[HN(CH₂)₁₁CO]-a-HN(CH₂)₁₂-NH-[OC(CH₂)₁₁-NH]b-(O:)C(CH₂)₁₆CH₃, in which a = 2-5 and b = 2,5. The compacted metal powder compns. (e.g., Distaloy AE with the lubricant and an optional flow enhancer, such as Aerosil 200) are sintered at >1050° to form the sintered product.

- AB The mixed powder contains (a) Fe-based powder, (b) graphite-containing powder for alloy, (c) 0.1-0.7% (based on total of a, b, and c) a machinability improver of alkaline earth metal fluoride powder, (d) a binder, and (e) a free-state lubricant, wherein the graphite powder and the machinability improver powder are fixed on the Fe-based powder with the binder. The sintered Fe alloy is obtained by press-forming the mixed powder and sintering the formed article. Since the machinability improver does not contain conventional S, S-derived furnace pollution and defect on the sintered alloy are prevented.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The Fe-based powder blends contain: (a) atomized and optionally reduced Fe powder base; (b) alloying metal powders; (c) temporary binder based on thermoplastic resin; (d) die-pressing organic lubricant and optional oil addition; and (e) optional additive for machinability of sintered article. The powder blends have pack d. ≥ 3.1 g/cm³, and controlled particle size distribution for die filling and compressibility without segregation. The Fe-powder particle size distribution is controlled for $\leq 18.5\%$ at < 45 μ m, 46% in the 75-150 μ m size range, and $< 10\%$ in the 150-180 μ m range with 180 μ m as the maximum size. The typical powder blend contains atomized Fe powder 70, reduction Fe powder 30, oleamide binder 0.20, stearamide binder 0.10, thermoplastic resin lubricant 0.10, and Li stearate lubricant 0.10 weight parts. The die-pressed preforms showed the green d. of 6.85 g/cm³, with a low segregation of graphite powder added for manufacture of sintered steel.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The rounded pellets are manufactured from powders by: (a) mixing the powder with organic material as a binder and lubricant; (b) heating the mixture above the m.p. of the organic material without vaporizing loss; and (c) rapidly cooling the hot mixture below the binder softening point, and simultaneously forming the rounded pellets from the cooling mixture. The associated resolidification improves the bonding of the powder particles. The process is suitable for the powdered metal, alloy, ceramic, glass, plastic, rubber, or composite. The organic binders are selected from a liquid and/or solid fatty acids, amides, soaps (or salts) of fatty acids, waxes, resins, oils, hydrogenated fats and oils, polymers, mold release, or friction-reducing agents. The pelletized feed can be poured into a die for molding, and the molded preforms can be ejected and heated to burn off the binder before sintering.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Near-net-shape soft magnetic components can be produced from Fe powder-lubricant comps. using powder metallurgy techniques. The resulting components have isotropic magnetic and thermal properties and may be shaped into complex geometry using conventional compaction techniques. A noncoated ferromagnetic powder is mixed with a lubricant and compacted. After compaction, the components are thermally treated at a moderate temperature to burn out the lubricant, and possibly also relieve the stresses induced during pressing and reduce the hysteresis losses. Depending on the application, the properties of the material may be tailored by varying the content and type of the lubricant and the thermal treatment conditions.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The mixture contains a Fe-base powder, a powder for alloying, a binder, a lubricant, and optionally a cutability enhancer. The Fe-base powder contains 60-90% atomized Fe powder and a reduced Fe powder as the balance. The alloying powder is secured to the surface of the Fe alloy powder with the binder. At least a part of the lubricant is present as a free lubricant. The mixture has excellent compressibility and filling ability. The binder is preferably a stearic acid, oleic acid amide, stearic acid

- amide, a molten mixture of stearic acid amide and ethylene bis-stearic acid amide, or ethylene bis-stearic acid amide.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Near-net-shape soft magnetic components can be produced from Fe powder lubricant compns. using powder metallurgy techniques. The resulting components have isotropic magnetic and thermal properties and may be shaped into complex geometry using conventional compaction techniques. A non-coated ferromagnetic powder is mixed with a lubricant and compacted. After compaction, the components are thermally treated at a moderate temperature to burn out the lubricant, relieve the stresses induced during pressing and reduce the hysteresis losses. Depending on the application, the properties of the material may be tailored by varying the content and type of the lubricant and the thermal treatment conditions.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB An iron-base powder mixture containing an iron-base powder, a lubricant having
been fused and adhered to the iron-base powder, a powder for an alloy adhered
to the iron-base powder through the lubricant, and a free lubricant powder,
characterized in that ≥ 1 of those components one or more of the above iron-
base powder, the above lubricant having been fused and adhered to the iron-

base powder, the above free lubricant powder, and the above powder for an alloy have a surface which is coated with an organosiloxane with a covering percentage of 80 or more. The iron-base powder mixture is excellent in flowability and formability, and also is reduced in the temperature dependency of flowability and green d. It is preferred that the organosiloxane has a Ph group, the lubricant having been fused and adhered to the iron-base powder is a co-molten product of a calcium soap with a lithium soap or a co-molten product of a calcium soap with an amide lubricant, and the free lubricant is a lithium soap or a mixed powder of an amide lubricant with a poly(Me methacrylate) powder.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The Fe-based powder blends for preform manufacture by warm (>120°) compaction include a lubricant powder as a polycarboxylic acid amide wax (I) having the m.p. of 180-210°. The powder blend is preheated to the temperature 5-50° below the I wax m.p., and is pressed in heated die to manufacture the preforms suitable for sintering at >1050°. The I wax is typically com. Lanco TPW-031. The powder blend based on Distaloy AE with 0.3% graphite and 0.6% I wax lubricant was pressed at 120-140° to the green d. of .apprx.3.11 g/cm3, vs. 2.99-3.05 g/cm3 using stearamide-type lubricant.

AB This powder mixture contains an Fe powder and a free lubricating agent powder which contains 0.02-1 weight% of an antistatic agent and which is mixed in the mixture in 0.1-0.5 weight%. Alternatively, the powder mixture further contains a metal powder for alloying and/or a powder for improving cutting property and another lubricating agent powder containing no antistatic agent in specified ratio. A powder mixture with a slightly different composition is also claimed. The lubricating agent powder may be stearic acid, oleic acid amide, stearic acid amide, a melted mixture of stearic acid amide and ethylenebis(stearic acid amide), ethylenebis(stearic acid amide), etc. The powder mixture is excellent in fluidity and compaction and easy to be handled and discharged from a hopper.

AB Lower melting temperature die wall lubricants could optimize die wall
 lubrication and help it further penetrate the powder metallurgy market. Die
 wall lubrication uses less lubricant (.apprx.0.05% vs. 0.75% internal
 lubricant) and provides a cleaner environment due to little or no lubricant
 burn-off during sintering. It also increases green strength and imparts lower
 d. variation and dimensional change of sintered parts. The objective of this
 study is to find lower melting temperature lubricants which become liquid
 during compaction (after coating the die wall) since lubricity increases
 (friction decreases) as a dry lubricant transforms into a liquid

AB The amount of lubricants in powder and their chemical composition have a significant influence on the performance of the material and the green and sintered properties of the powder- metallurgy (P/M) parts. Lubricants are necessary to provide numerous functions such as decrease ejection force, improve d. distribution, enhance flow rate and green strength and other. This paper discusses the influence of "original" lubricants such as zinc stearate, ethylenebisstearamide, lithium stearate, and stearic acid and their 50/50 % mixes on the material characteristic and green and sintered steel parts properties. A total of ten kind of lubricant mixes are studied. The amount of lubricant in all mixes was 1%. The lubricant type and composition should be considered for the new parts tool design and final mech. properties of the sintered parts.

AB The Al or Al-alloy powder for sintering is premixed with: (a) resin binder and/or wax at typically 0.1-1%, especially to decrease dusting and segregation; (b) optional lubricants; and/or (c) metal powders for addnl. alloying, or ceramic powders for composites. The Al master alloy powder is preferably premixed with polyvinyl alc. and/or paraffin wax as the binders. The Al-powder mixts. optionally contain metal and ceramic powders for the manufacture of sintered composites. The Al-alloy powder (containing Zn 8, Mg 2.5, Cu 1, and Pb 0.07%) was premixed with poly(vinyl acetate) binder, pressed in a steel die, and sintered at 600° in dry N2 atmospheric, resulting in the maximum sintered d. of .apprx.2.60 g/cm3 at 0.2-0.3% binder, and the maximum tensile strength (after age hardening) of .apprx.280 MPa at .apprx.0.1% binder.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The sintering mixts. based on Fe powder contain: (a) 0.05-0.50% of thermoplastic resin powder having the primary particle size of 0.03-5 μ m, and the average agglomerate size of 5-50 μ m; and (b) optionally 0.1-1.0% of liquid lubricant as a coating on the Fe-powder particles; and (c) optional graphite and alloying powders bonded to the Fe-powder particles. The polymer resin powder contains \geq 50 weight% of the monomers selected from acrylic esters, methacrylic esters, and/or aromatic vinyl compds., and has the average mol. weight (based on specific viscosity of solution) of 30,000-5,000,000. The resin powder is preferably poly(methylmethacrylate). The liquid lubricant coating contains stearic acid, oleamide, and/or stearamide. The Fe-powder blends with graphite and alloying metals are heated for effective mixing with the lubricants and resin powder, and cooled for storage. The resulting Fe-powder mixts. are flowable, show good resistance to component segregation, and do not contain conventional metal-soap lubricants as impurity source. The Fe-based powder mixts. with graphite and minor alloying metals (especially Cu) are suitable for preforms in manufacture of sintered steel parts.

AB The effects of P/M (powder metallurgy) lubricants on material flow, apparent d., compaction, ejection characteristics, and sintered properties were characterized for several pure compds. and composite lubricants (containing metal stearates and other additives) in the P/M processing of Ancorsteel 1000B with 2.9 weight% Fe3P. The findings identified key performance elements which provide a model for developing an improved P/M lubricant. Composite lubricants provided superior or equivalent powder, green, and sintered properties, compared with the industry standard, ethylene bisstearamide, lubricant. Especially, composite lubricants were capable of reducing the force required to eject the compact from the die. No one lubricant particle size satisfied all the requirements; fine lubricants provided higher d. and strength, whereas coarse lubricants reduced the ejection force required.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The lubricant mixts. for powder-metallurgy preforms contain: (a) Li salt of fatty acids at 10-60%, especially with the C12-28 fatty acids; (b) optional Zn salt of fatty acids at 0-40%; and (c) fatty acid bis-amides at 40-90%, preferably with ethylene bis-stearic acid amide (I) and similar compds. The molten lubricant mixture is suitable for powder manufacture. The typical lubricant added to atomized steel powder at 80 g/10 kg mix for green preform d. of 7.14 g/cm³ after pressing at 7 tons/cm² contained Li stearate 20, Zn stearate 15, and I 65%, vs. only 6.99 g/cm³ when using Zn stearate. The sintered d. after 30 min at 1120° was comparable to the green d.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The magnet is manufactured by kneading rare earth alloy powders with an aqueous binder containing ≥ 1 water-soluble polymer to prepare a slurry, spray-drying to form granulated powders, adding a fatty acid ester and/or a borate ester, press-molding, and sintering. The fatty acid ester and/or the borate ester works as lubricant(s). The method gives magnets with uniform weight and d.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The metal and/or alloy powder mixts. for high-d. green preforms for sintering include vinyl halide lubricant at nominally 0.2-0.6% for improved compaction. The preforms based on Fe or steel powders can be compacted at 30-50 ton/in.2, and are heated in H2 atmospheric to 400-700° to vaporize the lubricants, and then are heated to 1120-1265° for sintering. The lubricant mixture typically includes powdered polytetrafluoroethylene (I) as the vinyl halide, optionally with stearic acid, ethylene bis-stearamide, and/or Zn stearate. The green preforms for sintered steel articles have typical d. of 6.8-7.3 g/cm3, and can be sintered to 6.6-7.33 g/cm3. The preforms from Distaloy 4800A powder for sintered steel were compacted at 50 ton/in.2 (690 MPa), and with 0.4% I showed the green d. of 7.29 g/cm3 and sintered (1260°) d. of 7.31 g/cm3, vs. only 7.11 and 7.05 g/cm3 when the lubricant mixture was 0.1% I and 0.3% ethylene bis-stearamide.

AB The magnet is manufactured by these steps: coating a R-Fe-B alloy powder (R = Y-containing rare-earth element) with a boric acid ester, adding a binder of H₂O and Me cellulose, polyacryl amide, and/or poly(vinyl alc.) followed by kneading and mixing to form a slurry, granulating it for 20-400 µm-average grain size granules by spray dryer, and forming the magnet from the granules by powder metallurgy. The manufacture provides a compact sintered magnet with good size precision and less residual C concentration

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The green preforms for mech. assembly are alloyed to promote increased growth of the inner preform relative to the outer preform in sintering. The typical preform is pressed from the Fe-based powder mixture containing Cu, graphite powder, organic (especially amide) binders, and waxy or soap-type lubricants, with the inner Cu content higher than the outer content by $\geq 0.3\%$ to promote

increased expansion and better contact bonding. The binders are selected for fusing at 90-150° to precoat the Fe powder with Cu powder for improved surface alloying, and typically contain methylene bis-stearic acid amide and oleic acid monoamide at 1:1 weight ratio. The process is suitable for manufacture of sintered gears and similar articles from green assemblies with concentric preforms. The powder mixts. for sintered steel in manufacture of a flanged wheel are based on Fe powder, and contain: (a) Cu powder 3.0, graphite powder 1.0, and lubricant-binder combination 0.80% for the inner preform; and (b) Cu 1.5, graphite 0.9, and lubricant-binder 0.80% for the outer preform.

AB The title process comprises mixing an Fe powder with alloying powders and/or powders for cutability improvement and a binder containing a polyamide, polyvinyl butyral, and/or polyvinyl formal at >T, adding a powdered lubricant from a higher aliphatic acid amide, higher aliphatic acid alc., and/or higher aliphatic acid ester and mixing at ≥T but <T₁, where T and T₁ are m.p. of the binder and lubricant, resp. The segregation of additives is decreased, and stable supply of the mixture from a hopper is possible. Thus, a mixture was prepared containing Cu 1.5, graphite 0.9, stearic acid amide and ethylene bis-stearic acid amide as a lubricant 0.5, stearic acid as a binder 0.3%, and balance an Fe powder. The mixture showed good flowability and produced sintered products with good surface quality.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB Powder mixts. or additives (especially for alloying and/or improved machinability) are pre-coated on Fe-alloy powder by mixing with 0.1-1% organic binder, heating to melt the binder, cooling the mixture for binder solidification, and then mixing with 0.01-0.2% lubricant. The binders are fused mixts. of stearic acid, oleic acid monoamide, stearic acid amide, ethylenebisstearic acid amide, and/or methylenebisstearic acid amide, optionally with oleic acid, spindle oil, and/or turbine oil. The binders are optionally fused mixts. of higher fatty acid, higher fatty acid amide, and/or wax. The lubricants are Zn stearate or fatty-acid Li salt. The prepared powdered mixts. show good flowability for die filling as well as low segregation in preforming, and the obtained preforms are readily ejected from the dies.

ASSIGNMENT HISTORY FOR US PATENT AVAILABLE IN LSUS DISPLAY FORMAT

AB The Fe-alloy powder mixture for hot compaction at $\leq 370^\circ$ contains $\leq 15\%$ of amide lubricant as the reaction product of C6-12 linear dicarboxylic acid (preferably sebacic acid) and C10-22 monocarboxylic acid (especially stearic acid) 10-30 each with 40-80% of diamine (CH₂)₂-6(NH₂)₂ (especially ethylenediamine). The amide lubricants m. $\geq 150^\circ$. The powder mixts. for low-alloy steels preferably contain 0.1-1% amide lubricant, and can be compacted in heated dies at 25-55 tons/in.2 to manufacture the preforms for conventional sintering. A suitable com. amide lubricant is Advawax 450 (as ethylenebisstearamide) m. 200-300°. Thus, the green mixture based on Ancorsteel 1000 powder (with addition of powdered Cu 2, graphite 0.9, and Advawax 450 lubricant 0.7%) showed the green preform d. of 7.16 g/cm³ when pressed at 40 tons/in.2 and 150°, vs. 6.83 g/cm³ after the similar pressing at .apprx.20°. The preforms sintered in dissociated NH₃ for 30 min at .apprx.1120° showed the resp. d. of 7.08 vs. 6.73 g/cm³.

AB The injection molding compns. comprise metal or alloy powder and binder at (30-70):(30-70) volume ratio, and the binder comprises low-d. polyethylene, paraffin wax, and a lubricant selected from saturated alc., unsatd. fatty acid, fatty acid amide, and/or saturated fatty acid. The binder is easily removed after molding, and sintered products having dimensional uniformity are obtained. Thus, Fe-2%Ni alloy powder was mixed with 36 volume% binder containing low-d. polyethylene 20, paraffin wax 75, and capric alc. 5 weight%, injection molded, and sintered.

AB A microencapsulated lubricant, Caplube [81611-97-4], consists of polymer capsule containing .apprx.75 volume% fatty acid derivative liquid, and avoids the metal oxide contamination form the metal stearates. The lubricant contains only C, H, O, and N, and has good flow unlike the amide wax. With Fe powders the lubricant can have a synergistic effect in mixts. (e.g., with Zn stearate). Tests were run for powdered Fe, B-174 [81772-99-8] brass, and Cu with lubricants of graphite, Zn stearate, Li stearate, Acrawax C [8032-03-9], and Caplube.

AB Pressure-rupturable microcapsules for lubrication in powder metallurgy are disclosed that comprise a core of liquid lubricant enclosed by a thin polymeric solid shell. The microcapsules can be used as the sole lubricant in the manufacture of sintered metal parts, or they can be used in mixts. with other lubricants. Thus, a solution of 30 g tolylene diisocyanate in 120 g Me oleate [112-62-9] was added with stirring to a solution of 3 g Siponic 218 (a polyoxyethylene thioether) in 700 g water. When emulsification was complete, a solution of 30 g ethylenediamine in 70 g water was added, and the mixture was stirred for 4 h at 80°. After separation by filtration and drying at 60°, the microcapsules were white and free flowing with an average particle size of .apprx.50µ and a Me oleate content of .apprx.66%. Standard test methods with powdered Fe were used to compare the lubricant properties of the microcapsules with those of 2 com. lubricants, Zn stearate and ethylenebisstearamide [110-30-5]. The microcapsules were superior in injection force, apparent d., and shrinkage and were similar to the com. lubricants in tensile strength and transverse rupture strength.

AB Powdered Fe and other metallic compacts are more readily pressed to high d. in irregularly shaped molds if the powder mixture is well lubricated, and more liquid lubricant can be included in such a mixture, without impairing its free-flowing quality that is essential for com. production, if the mixture contains also fine particles of a porous gel to absorb lubricant in excess of the normal amount permissible for flow. Suitable gels for absorbing preferred surfactant lubricants such as oleic and similar fatty acids, fatty alcs., alkyl sulfonates, and sulfonated acids, esters, and amides, are activated C, kieselguhr, montmorillonite clays, fuller's earth, zeolites, and porous gels of SiO₂, Al₂O₃, and other oxides. They absorb only the excess lubricant, which can be made available by high pressure when needed, and in powder form do not interfere with flowability. Preferred oxide gels have at least 90 g oil absorption/100 g by standard ASTM tests, and usually .apprx.0.01-0.1 weight %, based on the metal powder, is a sufficient amount of silica gel for 0.1-0.5 weight % lubricant, on the same basis, for efficient lubrication with economy. The liquid lubricant can be added as a solution in acetone or benzene and added to the powder mixture of metal and gel with subsequent evaporation of the solvent, or the solvent can be omitted with vigorous mill blending. A solid lubricant such as Zn stearate can also be used. Numerous results of tests by standard ASTM methods are reported, comparing the properties of Fe powder mixts., compacts, and sintered articles made with various lubricant-binders. A typical comparison was powder-flow rate 35 sec, green d. 7.12 g/cm³, green strength 2550 psi, sintered d. 7.04, and sintered transverse strength 73,900 psi when the mixture contained Zn stearate 0.2, silica gel 0.05, and oleic acid 0.4%; when the silica gel was omitted the mixture would not pour through the standard test apparatus unless the oleic acid was also omitted. A mixture having only 1% Zn stearate lubricant was less dense and weaker, the properties being 31, 7.03, 1490, 7.00, and 67,100, resp.

AB Compacting lubricants used in powder metallurgy were studied with respect to their thermal decomposition under sintering conditions and their influence on the compactibility of Fe powder (improved d.) and the reduction of ejection force. Lubricants studied were stearic acid; its Zn, Mg, and NH_4 salts and esters; ethylenebisstearamide (I); poly-(Me methacrylate) (II) rubber latex; paraffin; and petrolatum. Addition of 0.25-1% stearates or I increased the d. of Fe powder only 0.2-0.3, whereas addns. of ($<50 \mu$) powdered lubricant significantly reduced the pressure required to expel the compact from the die, especially at very high (.apprx.2 kilobars) compacting pressures. The tensile strength, percent elongation, and magnetic permeability of sintered Fe powder compacted with 1% I were higher than when compacted with Zn stearate. A solid ZnO residue remained after decomposition of Zn stearate. The other lubricants after the dewaxing process at 250-400° also gave solid residues, m. .apprx.50-80°, except II and latex, which gave liquid monomer.

AB Lubricants effective during compression molding and the ejection of articles made from metal powders, are mixts. of 90-9.9 weight % amides or diamides of C10-32 aliphatic carboxylic acids and 0.1-10 weight % of a C6-32 alc. or diol or a polyethylene glycol with a mol. weight of 500-5000. A homogeneous mix was prepared of 33 g. Fe powder with 0.5 weight% of a lubricant, consisting of N,N'-ethylenebisstearamide 95 and 1,6-hexanediol 5 weight %. The mass was compression molded at 6000 kg./cm.2 into a 20-mm. diameter cylinder having a d. 6.72 g./cc. The specimen was ejected with a force of 154 kg./cm.2 When an equal amount of Zn stearate was the lubricant, the d. and the ejection force were 6.76 g./cc. and 272 kg./cm.2, resp. Fluidity comparisons on 50 g. of the powder mixts. through a given funnel were 34 sec. and 35 sec., resp. Also the 1st lubricant left no residue on burning while the 2nd left a deposit of metallic Zn.

AB Some factors affecting the sintering behavior of com. Fe powders are examined. The main groups are H-reduced roasted mill scale, CO-reduced magnetite, atomized pig iron decarburized either with Fe oxide or by an oxidation process, and electrolytic Fe powder. These powders show differences in their compressibility, sintering activity, and dimensional changes. Cylinders of carbonyl powder (1), H-reduced mill scale (2), sponge Fe powder (3), and electrolytic Fe powder (4) pressed at 40 tons/sq. in. had ds. of 6.60, 6.38, 6.63, and 7.06 g./cc., and green expansions of 0.21, 0.32, 0.27, and 0.20%, resp. Microscopically, (1) consisted of small equiaxed solid particles, (2) had a typical structure of H-reduced Fe₂O₃ with many very small partially isolated pores, (3) had larger pores typical of carbonaceous reduction at high temperature, and (4) was an agglomerate of nearly pure Fe particles. When 2 quantities of Fe in perfect contact are heated, there is an exchange of atoms between the 2 that reaches a maximum rate at 1670°F. when the α Fe transforms to γ . At 1670°F. the diffusion rate is lowered to 1/400 of the previous value, increases with rising temperature and reaches the previous maximum at 2200°F. The cylinders were heated 30 min. at temps. from 1000 to 2200°F. The d. increased up to the transformation temperature, decreased to a min. at 1800-1900°F., then increased at higher sintering temps. Bars presintered 0-40 min. at 1650°F. and given a final sinter at 2050°F. for 0 to 40 min. had maximum strength and elongation. To aid ejection of pressed compacts from the die, lubricants are added to the powder in amts. of 0.5-1.5%. The addition of 1% Ni stearate to Fe powder increased both tensile strength and elongation of sintered Fe powder compacts. Test bars containing either Li stearate, Zn stearate, steric acid, or amide wax as lubricants were pressed to increasing ds. and heated, to 1350°F. At low ds. the lubricant could escape. At 6.5 g./cc. and above, decomposition or charring took place in some cases. It is possible to design compns. of the different types of Fe powder with addns. of Cu and graphite to give zero or low dimensional changes on sintering.

AB Gluconamides can be easily functionalized to give a variety of compds. that form organogels with a high viscosity. N-n-octyl-D-gluconamide-6-benzoate gels a large variety of organic solvents, including 1,2-xylene, chloroform, Et acetate, and ethanol, to form gels which are, in some cases, stable even above the b.p. of the pure solvent. The 2-methoxy, 6-imidazolyl, 6-acetyl, and 6-cyclohexanoyl derivs. also show gelation, but the 2,4;3,5-dimethylene-protected derivs. do not. Detailed ¹H NMR, IR, and X-ray powder diffraction studies reveal that the mols. of most gelators are packed in a head-to-tail fashion. If there is, however, the possibility to form inter-layer hydrogen bonds, as in the case of N-n-octyl-D-gluconamide or N-n-octyl-D-gluconamide-6-(3-pyridyl carboxylate), the mols. are packed head-to-head. Some gluconamides, e.g., those with aliphatic substituents, express their mol. chirality in the supramol. structures, whereas others, in particular those containing a large aromatic substituent on carbon atom C6, yield nonchiral aggregates, probably due to interfering π - π stacking interactions of the substituents. DSC expts. show that the formation of the gels is an entropy-driven process.

GI

AB The crystal structure of N-(1-hexadecyl)-D-gluconamide I (n = 16) [a = 4.8072(6) Å, b = 46.771(5) Å, c = 5.2885(7) Å, β = 94.37(1)°; monoclinic P21, Z = 2] displays the same mol. conformation and the same monolayer packing-arrangement as its lower homologs described previously. This is at seeming variance with most recent CPMAS 13C NMR solid-state investigations describing a bilayer packing. It can be shown that the bilayer arrangement is the result of a kinetically driven crystallization process, whereas the monolayer packing is the thermodynamically stable polymorph of the title compound. Powder spectra of self-assembled layers of N-(1-alkyl)-D-gluconamides I (n = 9-18) showed only one-dimensional order and exhibited at most two periodicities. These

could be assigned to a mono- and bilayer arrangement, resp. Derivs. with long alkyl chains proved to have a smaller tendency towards monolayer assembling than homologs with a short tail.

AB Nonionic surfactants CH₂(OH)[CH(OH)]₄CONRR1 (R = C₈-22 alkyl, alkenyl; R1 = H, Me) are manufactured by treating glucono-δ-lactone (I) and a primary or secondary amine HNRR1. Thus, a mixture of I 187, laurylamine 184, and DMF 500 g was treated at 90° for 5 h, cooled, washed, and dried to give 358 g white powder comprising C 59.7, H 9.9, N 3.9, and O 26.5%, with amine value 0.3 and OH value 775.0. A polyester textile impregnated in a 1% solution of the powder showed surface elec. resistance 1.2 + 10⁹ Ω vs. 2.3 + 10¹⁵ Ω for a blank.

AB N-stearyl-D-gluconamide (I) [18375-66-1] and(or) N-octyl-D-gluconamide [18375-61-6] were useful as mold release agents in aminoplast molding comps. Thus, a mixture of 3% HCHO 100, hexamine 4.5, and urea 55 parts was heated 50 min at 60.deg., cooled, and mixed with NH₄Cl 0.12, Zn stearate 0.1, and α -cellulose 35 parts. The mixture was dried to a 2% water content, and the dried material (100 parts) was mixed with I 0.2, TiO₂ 0.2, and pigments 0.13 part and ball-milled to give a molding powder. The powder was molded at 145-50.deg. to give small moldings at a rate of 120 pieces/hr, compared with 90 pieces/hr for a similar molding powder containing Zn stearate in place of I.

AB Thermoplastic and thermosetting molding compns. with improved processability, mold release properties, and antistatic properties are prepared by addition of 0.01-20% N-alkylgluconamides, RNHCO[CH(OH)]₄CH₂OH (I), where R is C₂-18 alkyl. Thus, an acrylonitrile-butadiene-styrene resin is blended 2 min with 2% I [R = (CH₂)₁₇Me] at 180° to yield a molding composition with improved flow properties. Other resin compns. with improved processability, thermal stability, mold release properties, and antistatic properties are obtained by blending poly(vinyl chloride), poly(Me methacrylate), polyethylene, polystyrene, urea resins, melamine resins, or phenolic resins with the following I (R given): Et, pentyl, octyl, dodecyl, decyl, hexadecyl, pentadecyl, 2-ethylhexyl, nonyl.

AB cf. CA 56, 5125a. From fresh *M. charantia* fruit was obtained pure D-galacturonic acid. From 1280 g. fruit, after repeated extraction with hot EtOH, was obtained 72 g. powder. The solution of Ba D-galacturonate prepared from the powder was added to absolute EtOH without previous concentration in vacuo. The crude precipitated Ba D-galacturonate (I) was purified by solution in H₂O and precipitation with absolute EtOH to give pure I (0.71 g.). I (0.4 g.) was treated with H₂SO₄, filtered, concentrated in vacuo, triturated with dry Me₂CO, and recrystd. from dilute EtOH and from Me₂CO to give 0.1 g. D-galacturonic acid, m. 155°. I and quinine sulfate in absolute EtOH gave quininium D-galacturonate, m. 218-19° (decomposition). Similarly were prepared atropinium D-galacturonate, m. 78-80°, and anilinium D-galacturonate (only as the crude).

AB C18H37OH (10.8 g.) in 180 cc. CHCl₃ added slowly with vigorous stirring and cooling to 6 cc. PhP(O)Cl₂ in 16 cc. CHCl₃ and 3.4 cc. pyridine, the mixture warmed 10 min. at 35°, treated with 5.6 g. dry powdered HO(CH₂)₂NMe₃Cl, stirred 48 hrs. at room temperature, and evaporated, the residue extracted with three 50-cc. portions Et₂O, the insol. residue dissolved in 50 cc. H₂O, the solution saturated with NaCl and extracted with CHCl₃, and the extract evaporated yielded 7 g. C18H37OP(O)(OPh)OCH₂CH₂NMe₃Cl (I), m. 82-6° (from Me₂CO). I (3.0 g.) hydrogenated in EtOH over PtO₂ yielded 1.8 g. C18H37OP(O)(OH)OCH₂CH₂NMe₃Cl (Ia) m. 71-2° (from Me₂CO). Ia in EtOH treated

with Amberlite IRA-400, the solvent partially removed, the residue diluted with Me₂CO, and the crude precipitate chromatographed and eluted with 4:1 CHCl₃-EtOH gave the corresponding hydroxide, m. 220-30°; it is sparingly soluble in H₂O and Nujol at room temperature and shows no emulsifying properties. Dihydrophytyl and cholestanyl phosphorylcholine were prepared in essentially the same manner but could not be obtained pure; the crude dihydrophytyl derivative (semisolid) showed some emulsifying action. L-Arabinose (75 g.) in H₂O treated at room temperature 12 hrs. with 120 g. Br, the excess Br removed in vacuo at 40-50°, the mixture treated with 120 g. PbO, the white precipitate filtered off after several hrs., the filtrate treated dropwise with H₂SO₄ and filtered, concentrated in vacuo at 50°, and the residue diluted with 75 cc. MeOH and allowed to stand a few hrs. at 5° deposited 77% arabinonolactone (II), m. 148-50° (from MeOH), αD₂₀ -6.5°. II (2 g.) in MeOH treated with 2.2 g. Cl₂H₂₅NH₂ and kept at room temperature deposited 87.5% N-laurylarabonamide, m. 150-1° (from EtOH or dioxane). Similarly were prepared the following N-alkylarabonamides (alkyl group and m.p. given): C₁₀H₂₁, 150-1° (from EtOH); C₁₄H₂₉, 150-1° (from EtOH); C₁₆H₃₃, 150-1° (from dioxane); C₁₈H₃₇, 149-50° (from dioxane). Gluconolactone condensed with C₁₈H₃₇NH₂ (IIa) at 140° or in refluxing EtOH during 1 hr. gave N-stearylgluconamide, m. 149.4-54.8° (from EtOH). Similarly were prepared the following N-alkylgluconamides (III) (alkyl group and m.p. given): C₁₂H₂₅, 153.2-5.6°; C₁₆H₃₂, 150.4-4.6°. Glucoheptonolactone (2.08 g.), m. 148-52°, and 2.69 g. IIa gave similarly 55% N-stearylglucoheptonamide, m. 149-52° (cloudy) (from EtOH); it decomposed at about 180°. The C₁₄-, C₁₆-, and C₁₈-III gave a solubility of about 6 g./l. boiling H₂O; when used with cholesterol or the mono-stearyl ether of (CH₂OH)₂ emulsions with an average particle size of 5-10 μ can be obtained in a Waring Blender; these emulsions are stable only for a few hrs. 1,2-Isopropylideneglucuronolactone (IV) was prepared in 81% yield by the method of Owen, et al. (C.A. 35, 6240.2), except that the volume of Me₂CO was reduced to 500 cc. for 20 g. IV and Na₂CO₃ was used instead of BaCO₃. IV (6.6 g.) in 50 cc. dioxane and 15 cc. cold concentrated NH₄OH kept 4-5 hrs. in the cold room, and the solution evaporated in vacuo below 45° gave almost 100% 1,2-isopropylideneglucuronamide (V), needles, m. 163-4° (from absolute EtOH), αD₁₈ -13.5° (c 1, H₂O). IV (5.8 g.) in 50 cc. dry tetrahydrofuran treated with 6.8 g. IIa in small portions with stirring, kept overnight in the cold room, and then a few hrs. at room temperature, the solvent removed in vacuo below 40° to incipient crystallization, and the residue diluted with petr. ether gave 8.0 g. 1,2-isopropylidene-N-stearylglucuronamide (VI), m. 92-3°; 2nd crop, 2.3 g., m. 86-90°. Similarly were prepared the following 1,2-isopropylidene-N-alkylglucuronamides in 70-90% yield (alkyl group, m.p., and αD in MeOH given): C₁₀H₂₁, 70-5° (from petr. ether), -14° (c 1.162); C₁₂H₂₅, 87-8° (from MeOH), -13° (c 1.046); C₁₄H₂₉, 88-90° (from MeOH), -12.5° (c 1.09); C₁₆H₃₃, 90-2° (from EtOH), -13.5° (c 1.064). ω-Cyclohexyldecanic acid (10 g.) refluxed 2 hrs. with 15 cc. SOCl₂ and evaporated in vacuo, and the cooled residue poured slowly into 100 cc. ice-cold concentrated NH₄OH yielded 9 g. ω-cyclohexyldecanamide (VII), m. 89-93° (from aqueous MeOH). VII (7.6 g.) reduced in the usual manner with LiAlH₄ in refluxing Et₂O and the Et₂O solution treated with HCl gave 6.3 g. ω-cyclohexyldecylamine HCl salt, m. 151-3° (from MeOH); free base, m. above 50°. The free amine in Et₂O (liberated with aqueous NaHCO₃ from the HCl salt) treated with IV gave 1,2-isopropylidene-N-(ω-cyclohexyldecyl)glucuronamide, m. 88-90°. V (2.3 g.) in 20 cc. H₂O and 0.5 cc. concentrated HCl heated 1-3 min. at 80°, the H₂O removed in vacuo, and the residue crystallized from absolute MeOH gave 1.8 g. glucuronamide (VIII). H₂O, m. 168-9° (decomposition), αD₂₂ 70° → 31.9° (44 hrs., c 1.77, H₂O); anhydrous VIII, m. 173-4°. γ-Lactone of β-methylglucuronoside (4.2 g.) in 20 cc. cold dioxane treated overnight with 10 cc. ice cold NH₄OH (d. 0.9), the solvent removed in vacuo below 40°, and the residue hydrolyzed with HCl gave 2.1 g. VIII. H₂O. VI (5 g.) in 100-350 cc.

H₂O and 7 cc. concentrated HCl tested with stirring 30-45 min. on the steam bath and the mixture cooled gave the corresponding N-alkylglucuronamides (alkyl group, m.p., and α D in MeOH given): C10H₂₁, 145-8° (decomposition) (from aqueous MeOH), 24° (c 1.11); C12H₂₅, 160-1° (from aqueous dioxane), -4° → 22° (24 hrs., c 1.18); C14H₂₉, 156-7° (from aqueous dioxane), 11° → 24° (24 hrs., c 1.05); C16H₃₃ (IX), 155-7° (from aqueous dioxane), 24.7° → 26° (24 hrs., c 1.03); C18H₃₇ (X), 153-4° (from aqueous dioxane), 23° (10 min., c 1.046); ω -cyclohexyldecyl (XI), 128-30° (from MeOH), 21° → 25° (24 hrs., c 1.15). ω -Cyclohexylbutyramide, m. 103-6°, reduced to the amine (HCl salt, m. 165-7°), condensed with V, and the product hydrolyzed yielded 80% ω -cyclohexylbutylglucuronamide, m. 160-3° (from aqueous MeOH), α D 35.8° → 23.5° (24 hrs., c 1.54, MeOH). IX, X, and XI gave fairly stable oil-in-water emulsions when used with a co-emulsifier. IIA (2.5 g.) in 15 cc. cold tetrahydrofuran added to 2 g. β -methylglucuronoside- γ -lactone in cold tetrahydrofuran, the mixture kept overnight in the cold room and then 1-2 hrs. at room temperature, and the solvent removed in vacuo yielded 77% N-stearylamide (XII) of β -methylglucuronoside (XIII), m. 75-8° (from Et₂O), α D 21-60.4° (c 1.03, MeOH). A similar run carried out at an initial temperature of 40-50° for 0.5 hr. and then at 25° for 2-3 hrs. yielded 87% higher melting form of XII, m. 93-5° (from MeOH-C₆H₆), α D 25-60.7° (c 1.0, MeOH). Similarly were prepared the following N-alkylamides of XIII (alkyl group, m.p., and α D in MeOH of form A and B given): C12H₂₅, 68-70°, -58.4° (c 1.05), 88-90°, -58.7° (c 1.43); C14H₂₉, 70-3°, -60.8° (c 1.11), 88-90°, -61° (c 1.04); C16H₃₃, 75-8°, -60.6° (c 1.3), 92-3°, -60.5° (c 1.3). The glucuronosides were hydrolyzed with 1 cc. concentrated HCl in 100 cc. H₂O to the corresponding glucuronamides in nearly 100% yield. The appropriate glucuronamide (5 g.) in 250-500 cc. hot H₂O treated at 50-60° with 4 cc. Br at 40-50°, the solution kept in the cold room overnight, the excess Br removed with saturated aqueous Na₂S₂O₃, and the product air-dried and recrystd. from tetrahydrofuran gave about 80% of the corresponding N-alkylglucosaccharonamide (XIV) (alkyl group, m.p., and α D in tetrahydrofuran given): C12H₂₅, 134-7°, -21.5° (c 1.13); C14H₂₉, 125-7°, -22° (c 1.06); C16H₃₃, 135-8° with previous sintering, -21° (c 1.14); C18H₃₇, 137-9°, -22° (c 1.12). The XIV gave less stable emulsions than the corresponding glucuronamides; they are slightly more H₂O-soluble. C11H₂₃COCl (2.2 g.) in 20 cc. tetrahydrofuran added dropwise with stirring to 2.15 g. glucosamine.HCl salt and 2 g. NaHCO₃ in 20 cc. H₂O with agitation, the mixture agitated 0.5 hr. and diluted with 100 cc. H₂O, and the precipitate washed with H₂O and recrystd. from dioxane-EtOH gave 3.2 g. N-lauroylglucosamine, m. 190-3°. Similarly were prepared the following N-acylglucosamines (XV) (acyl group and m.p. with decomposition given): C13H₂₇CO, 193-5° (from dioxane-EtOH); C15H₃₁CO, 190-3° (from dioxane-EtOH); C17H₃₅CO, 190-1° (from dioxane-EtOH). C17H₃₅CO₂H (XVI) (11.4 g.) and 6 cc. Et₃N in dry tetrahydrofuran treated with stirring and cooling at -5° with 4 cc. ClCO₂Et and then after 5 min. without further cooling with the Na salt of 3.6 g. β -alanine in 30 cc. cold H₂O, the mixture stirred 0.5 hr., acidified to pH 3-4, and filtered, and the residue washed with warm H₂O, dried, extracted with petr. ether, and recrystd. from 4:1 dioxane-H₂O or tetrahydrofuran yielded 11.2 g. stearoyl- β -alanine (XVII), m. 122-4°, insol. in H₂O at 25°, somewhat soluble at 100°. In the same manner was prepared oleoyl- β -alanine (XVIII), m. 75-6° (from aqueous dioxane). XVIII (1 g.), 1.2 g. AgOAc, and 13 cc. glacial AcOH containing 0.1 cc. H₂O treated during 40 min. with 0.72 g. iodine, the mixture heated 3 hrs. on the steam bath, cooled, filtered, and evaporated, the residue in MeOH refluxed 25 min. with aqueous KOH and filtered, and the filtrate acidified gave 0.6 g. 9,10-dihydroxystearoyl- β -alanine, m. 148-50° (from EtOH). XVII was converted in the usual manner in 71% yield to stearoyl- β -alanyl- β -alanine, m. 153-6° (from aqueous dioxane). Similarly were prepared: stearoyl- β -alanylglycine, 75%, m. 172-4° (from

dioxane-H₂O); stearyl- β -alanyltaurine, 78%, m. about 200° (decomposition) (it contains solvent of crystallization which is not removed by drying at 150°). XVI (3 g.), 1.07 g. Et₃N, and 1.44 g. ClCO₂CH₂CHMe₂ in CHCl₃-EtOAc treated with 1.62 g. α -alanine Et ester (XVIIa) HCl salt and 1.07 g. Et₃N gave 2.87 g. stearyl- α -alanine Et ester (XIX), m. 62-5° (from ligroine). XIX (1 g.) in 10 cc. dioxane hydrolyzed with 3 cc. concentrated HCl in 1.5 cc. H₂O on the steam bath during 1 hr. yielded 0.63 g. DL-stearyl- α -alanine (XX), m. 115-17° (from ligroine-dioxane). XX and XVIIa were converted by the mixed anhydride method to stearyl- α -alanyl- α -alanine Et ester, m. 82-3°, which was hydrolyzed to the free acid, m. 132-3° (from petr. ether-dioxane). Similarly were prepared the following compds. (% yield and m.p. given): stearylglucine (XXI), 75-80, 125-7° (from EtOAc-tetrahydrofuran); stearylglucyl- β -alanine, 70-5, 169-70° (from dioxane); stearylglucylglycine, 75-80, 170-2° (from dioxane); stearylglucyltaurine, 80-90, -(practically insol. in various organic solvents; it crystallized from H₂O with H₂O of crystallization which is not lost by drying at 150°); stearyltaurine, 73, m. about 240° (decomposition); stearyl-DL-asparagine (XXII), 70, 145-8° (from dioxane); stearylglucylasparagine (XXIII).H₂O, 70-5°, 180-5° (from aqueous dioxane). XXII (0.4 g.) in 10 cc. dioxane treated with 0.08 g. NaNO₂ in 30 cc. H₂O, warmed 4-6 hrs. on the steam bath with 0.4 cc. concentrated HCl, and cooled to room temperature deposited 0.37 g. stearyl-DL-aspartic acid (XXIV), m. 111-13° (from aqueous dioxane or EtOAc). XXIV heated 15 min. at 70-80° in Ac₂O and cooled gave 100% stearyl-DL-aspartic anhydride, m. 124-5° (from ligroine containing some tetrahydrofuran). Stearyl-L-glutamic acid, m. 127-8° (from tetrahydrofuran), α D₂₂ 8.5° (c 1.62, dioxane), was prepared in 55% yield by the mixed anhydride method from L-glutamic acid and then converted in the usual manner to the anhydride, m. 107-9° (from ligroine-tetrahydrofuran). XXIII hydrolyzed with acid in the presence of NaNO₂ yielded 80-90% stearyl-DL-aspartic acid, m. 165-70°; also prepared in 40-60% yield directly from XXI; the acid was converted in the usual manner to the anhydride, m. 175-80°. Cl₈H₃₂CHBrCO₂H (10 g.) heated 24 hrs. with excess 27% NH₄OH in a pressure bottle and the product washed with H₂O and boiling MeOH and ligroine gave 8.5 g. Cl₆H₃₃CH(NH₂)CO₂H (XXV), m. 223-4° (decomposition). XXV heated with phthalic anhydride 0.5 hr. at 145-60° gave the phthalimido derivative (XXVI) of XXV, m. 81° (from ligroine). XXVI (2 g.) refluxed 3 hrs. with 10 cc. SOCl₂, the excess SOCl₂ removed with suction, the residual oil washed with dry PhMe, dried at 1 mm., dissolved in 20 cc. dry CHCl₃, and treated with 0.71 g. Et ester of α -alanine HCl salt in 10 cc. dry CHCl₃, the mixture cooled to -20°, treated with stirring during 40 min. with 1.1 g. Et₃N in dry CHCl₃, warmed to room temperature, and evaporated in vacuo, and the residue dissolved in ligroine, washed with H₂O, evaporated, and diluted with petr. ether yielded 0.9 g. Et ester (XXVII) of α -phthalimidostearyl- α -alanine (XXVIII), crystals, m. 63-4°; XXVIII, m. 116° (from ligroine). XXVIII (0.45 g.) in 7 cc. 95% EtOH refluxed 45 min. with 1.5 cc. N₂H₄ and a few drops H₂O, cooled, and diluted with H₂O gave 0.28 g. α -aminostearyl- α -alanine, m. 218-20°. N-Carbobenzoyloxy-DL-alanine (4.46 g.), m. 120-2° in 50 cc. tetrahydrofuran containing 3 cc. Et₃N treated with stirring at -5° with 5.4 g. Iia in 50 cc. tetrahydrofuran, the mixture stirred 0.5 hr. without cooling and acidified, the solvent partially removed in vacuo, the residue diluted with cold H₂O, and the precipitate washed with cold dilute NH₄OH and recrystd. from MeOH yielded 8 g. N-carbobenzoyloxy-DL-alanylstearylamine (XXIX), m. 106-9°. XXIX (4.7 g.) in 100 cc. absolute MeOH hydrogenated overnight over 0.25 g. 10% Pd-C, filtered, and evaporated, and the residue heated a few hrs. at 80-90° gave DL-alanylstearylamine (XXX), m. 76-8° (from MeOH). Similarly were prepared the following dipeptides (m.p. and m.p. of the N-carbobenzoyloxy derivative given): L-isomer of XXX, 70-3° (from Et₂O), 103-4° (from MeOH); L-alanylacetylamine.0.5 H₂O, 58-60° (from Et₂O), m. 90-20° (from MeOH); L-alanyl- ω -cyclohexyldecylamine, 56-8° (from MeOH), 115-16° (from MeOH); L-

leucylstearylamine, 66-8° (from MeOH), (hemihydrate) 96-8° (from MeOH); L-leucylcetylamine, 58-60° (from MeOH), 95-7° (from MeOH); L-propylstearylamine, 70-2° (from MeOH), 88-90° (from MeOH); glycylstearylamine hemihydrate, 96-8° (from MeOH), 116-18° (from tetrahydrofuran); glycylcetylamine, 84-6° (from MeOH), 110-11° (from MeOH); β -alanylstearylamine hemihydrate, 85-7°, 124-6° (from tetrahydrofuran-MeOH) [carbamate, m. 126-7° (from MeOH)]; β -alanylacetylamine hemihydrate, 84-6° (from Et2O), 124-6° (from dioxane-MeOH) [carbamate, m. 112-14° (from MeOH)]. N-Carbobenzoyloxy-L-cysteinylstearylamine, m. 156-61° (from tetrahydrofuran) reduced with Na in liquid NH3 yielded 40% N-cysteinylstearylamine, m. 74-6°. N-Carbobenzoyloxyaspartic acid anhydride (7.56 g.) in 35 cc. PhCH2OH treated 1 hr. with cooling with 1 equivalent PhCH2ONa yielded 7 g. PhCH2OC(=O)NHCH(OC(=O)CH2Ph)CH2CO2H which condensed with Iia via the mixed anhydride with ClCO2Et gave the dicarbobenzoyloxy derivative of N-stearyl-L-asparagine (XXXI), m. 92-4° (from MeOH); this treated with MeOH with H over Pd-C gave 60% XXXI, m. 168-70° (from MeOH). N-Carbobenzoyloxy-L-alanine condensed with L-alanylstearylamine followed by hydrogenolysis gave 80% L-alanyl-L-alanylstearylamine, m. 115-17° (from MeOH); N-carbobenzoyloxy derivative, m. 163-4° (from tetrahydrofuran and MeOH). Similarly was prepared β -alanyl- β -alanylstearylamine monohydrate, m. 160-3°; carbobenzoyloxy derivative, m. 175-8°. (CH2OH)2 (84 cc.), 1.5 g. Na, 20 g. C18H37Br, and 10 cc. tetrahydrofuran heated 96 hrs. at 120°, cooled, diluted with H2O, and extracted with Et2O gave 4.3 g. distearyl ether of (CH2OH)2, m. 55-7°; concentration of the mother liquors yielded 11.7 g. monostearyl ether (XXXII) of (CH2OH)2, white flaky solid, m. 51-2°. C18H37O(CH2)2CO2H (XXXIII) treated with LiAlH4 gave a product contaminated with C18H37OH (XXXIV). XXXIV (27 g.) added to 13 g. CH2=CHCO2Me in dry dioxane containing a trace of piperidine and PhCH2NMe3Br, the mixture refluxed overnight, concentrated, and diluted with H2O, the crude product washed with H2O and refluxed with 8 g. KOH in 500 cc. H2O, filtered, and acidified, the precipitate dissolved in Et2O, the solution treated with gaseous NH3, and the precipitate dissolved in H2O and acidified gave 4.5 g. XXXIII, m. 75-8° (from Et2O). XXXIII (1.7 g.) in dry tetrahydrofuran containing a trace Et3N treated at 0° with 0.5 cc. ClCO2Et, diluted after a few min. with absolute MeOH, and warmed to room temperature with stirring gave 1.7 g. Me ester of XXXIII, m. 53-6°, which was converted with concentrated NH4OH to the amide of XXXIII, m. 95-7° (from tetrahydrofuran-Et2O). The emulsion tests were carried out by dissolving the substance in 20 cc. H2O (employing generally the maximum concn), and mixing the solution in an Omnimixer with 5 cc. Nujol containing 0.2 g. cholesterol.

BASIC ABSTRACT:

JP 2006182964 A UPAB: 20060825

NOVELTY - A lubricant contains N,N'-alkylene bis(carboxylic acid monoamide) of beta-type crystal form.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is included for powder metallurgy method, which involves carrying out electrical charging adhesion of lubricant with respect to inner surface of metal mold.

USE - For metal mold adhesion in powder metallurgy (claimed).

ADVANTAGE - The lubricant has favorable electrical charging adhesion property. The adhesion of fixed quantity of lubricant with respect to inner surface of metal mold is enabled. The release property of molded product is improved.

TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Composition: The ratio of alpha-type crystal form and beta-type crystal form of N,N'-alkylene bis(carboxylic acid monoamide) is

30:70-0:100. The lubricant further contains carboxylic acid metal salt and carboxylic acid monoamide

. Preferred Property: The lubricant has average particle diameter of 0.1-200 microns.

EXTENSION ABSTRACT:

EXAMPLE - N,N'-Ethylene bis(stearic acid monoamide) and lithium stearate were mixed in ratio of 70:30, and heated at 170-180degreesC for 5 minutes. The molten material was cooled and solidified. The solid product was ground, classified and refined to produce lubricant. The lubricant had favorable electrical charging adhesivity.

BASIC ABSTRACT:

US 20060090393 A1 UPAB: 20090910

NOVELTY - Improving anti-corrosive, anti-fatigue and anti-wear properties of lubricants and hydrocarbon fuels involves adding at least one epoxidized ester.

DETAILED DESCRIPTION - Improving anti-corrosive, anti-fatigue and anti-wear properties of lubricants and hydrocarbon fuels involves adding at least one epoxidized ester of formula (I).

m=1 - 36;

R2=T;

T=hydrocarbyl group (optionally substituted by (cyclo(alkyl), alkenyl, aryl or alkoxy), H, OH, ether or epoxide;

R1 =T, R30-(CH2)n-CH2-, R30-CH(R5)-CH(R4)-, R30-R6-, -CH2-CH(R30)-CH2-OR7, -CH2-CH(CH2-OR7)(CH2-OR3)(CH2-OR8), -R6-C(OR7)(R9)(OR3), -C(OR7)(R9)(OR3) or -C(CH2-OR7)(CH2-R30)(R9);

n=0 - 12;

R4, R5 and R9=H or hydrocarbyl;

R6=linear alkylene, branched alkylene, linear alkenyl or branched alkenyl;

R3, R7 and R8=H or R10-C(=O)-;

R10=optionally substituted hydrocarbyl.

An INDEPENDENT CLAIM is included for a composition comprising a lubricant or a hydrocarbon fuel and the epoxidized ester.

USE - For improving anti-corrosive, anti-fatigue and anti-wear properties of lubricants and hydrocarbon fuels (claimed).

ADVANTAGE - The epoxidized ester improves functional properties, imparts anti-corrosive properties to the lubricant which protects lead and copper from corrosion and imparts protection to the lubricated system against the corrosive tendencies of other additives that might otherwise be desirable to add to the lubricant. TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Components: The composition further comprises an additive which is corrosive to lead and/or copper. The additive is selected from glycerol monooleate, partially hydrolyzed vegetable oils, full and partial esterification products of diols and polyols optionally with 6-36C carboxylic acids, 6-50C carboxylic acids, amides derived from 6-50C carboxylic acids, esters of hydroxypolycarboxylic acids, tetraalkyl thiuram disulfides, thionamides, thiourea, dithiocarbamates, hydrazides, succinylhydrazides, 4-imidazolidine thiones, 1,3,4-oxadiazole-2(3H)-thiones, 1,3,4-thiadiazolane-2-thiones, 2,3-dihydro-1,3,4-oxadiazoles and mixed thio acid amide molybdenum complexes. The epoxidized ester is an epoxidized vegetable oil, epoxidized soybean oil, and/or epoxidized canola oil. The corrosive additive is glycerol monooleate, trimer of citric acid, dithiocarbamate and thiuram disulfides.

EXTENSION ABSTRACT:

SPECIFIC COMPOUNDS - Epoxidized 2-ethylhexyl tallate is specifically claimed as the epoxidized ester.

EXAMPLE - No relevant example given.

BASIC ABSTRACT:

US 20050178190 A1 UPAB: 20051223

NOVELTY - Screening (M1) lubricating oil composition samples for dispersancy performance under program control, comprises: providing several lubricating oil composition samples, each comprising a major amount of at least one base oil of lubricating viscosity, minor amount of at least one lubricating oil additive, and a predetermined amount of base oil-insoluble material; measuring the dispersancy performance of each test sample; and outputting the results.

DETAILED DESCRIPTION - Screening (M1) lubricating oil composition samples for dispersancy performance under program control involves:

(a) providing several different lubricating oil composition samples, each sample comprising a major amount of at least one base oil of lubricating viscosity (i), a minor amount of at least one lubricating oil additive (ii), and a predetermined amount of a base oil-insoluble material (iii);

(b) measuring the dispersancy performance of each test sample to provide corresponding dispersancy performance data results; and
(c) outputting the results of step (b).

INDEPENDENT CLAIMS are also included for:

(1) a system for screening lubricant performance, under program control comprising: several test receptacles, each receptacle containing a different lubricating oil composition sample containing (i), (ii) and (iii); receptacle moving device for individually positioning the test receptacles in a testing station for measurement of dispersancy performance of the respective sample; and device for measuring the dispersancy performance of the sample in the testing station to obtain dispersancy performance data associated with the sample and for transferring the dispersancy performance data to a computer controller; and

(2) a combinatorial lubricating oil composition library comprising lubricating oil composition dispersancy data for several different lubricating oil compositions containing (i), and at least one lubricating oil additive.

USE - For screening lubricating oil composition samples for dispersancy performance under program control (claimed) useful in passenger cars and heavy-duty diesel engine oils.

ADVANTAGE - The method effectively screens lubricating oil composition samples and tests dispersancy of the composition automatically by utilizing small amounts of each sample. The method is more efficient, economical and provides a systematic approach for the preparation of lubricating oil compositions and screening of the compositions for information correlating to the actual useful properties of the composition. The method permits screening of many different composition samples in an efficient manner to determine optimal dispersancy characteristics of the samples.

TECHNOLOGY FOCUS:

MECHANICAL ENGINEERING - Preferred Components: The base oil is natural or synthetic oil. At least one lubricating oil additive is selected from antioxidants, anti-wear agents, detergents, rust inhibitors, de-hazing agents, demulsifying agents, metal deactivating agents, friction modifiers, pour point depressants, antifoaming agents, co-solvents, package compatibilizer, corrosion-inhibitors, ashless dispersants, dyes, and/or extreme pressure agents (preferably ashless dispersant). The base oil-insoluble material is a polar base oil-insoluble material (preferably sludge); or is natural soot, synthetic soot (preferably carbon black), varnish-forming material and/or water (preferably natural or synthetic soot). The sludge is recovered, used engine oil. The at least one lubricating oil additive further comprises a diluent oil.

Preferred Method: The step of measuring the dispersancy performance of each sample involves: either measuring the kinematic viscosity of each sample at a predetermined temperature; or applying to a respective piece of a chromatographic material at least one spot of each sample or dividing the sample into first and second portions, adding a predetermined amount of water to the second portion, applying to respective pieces of a chromatographic material at least three spots of each of the first and second portions of sample, heating selected spots to a predetermined temperature for a predetermined period of time; permitting the spot to elute into concentric rings; measuring an outer diameter of each ring and an inner diameter of each ring; calculating a ratio of inner diameter to outer diameter for the rings; and calculating dispersancy performance data based upon the ratios for the rings. (M1) further involves providing corresponding lubricating oil composition reference samples containing no base oil-insoluble material; measuring the kinematic viscosity of the corresponding reference samples; and determining the percentage difference between the

kinematic viscosity of the lubricating oil composition sample and the corresponding lubricating oil composition reference sample. The step of measuring the outer diameter of each ring and the inner diameter of each ring involves transmitting a light through light and dark areas of the chromatographic material (preferably filter paper). (M1) additionally involves: a step of homogenizing the samples prior to measuring the dispersancy performance. The step of homogenizing the samples is performed by mechanical stirring or by ultrasonic agitation. The step (c) of automatically outputting the results of step (b) involves converting the dispersancy performance data of step (b) into a digital signal and sending the digital signal to a microprocessor. The method further involves step of compiling the dispersancy performance data sent to the microprocessor in an electronically stored database and constructing from it a combinatorial lubricating oil composition library.

Preferred Composition: The lubricating oil composition sample has a volume not greater than 50 (preferably not greater than 20, especially not greater than 15, particularly not greater than 10) ml.

Preferred System: The system further comprises a bar code reader. The receptacle-moving device comprises a movable carriage, or a robotic assembly having a movable arm for grasping and moving a selected individual receptacle. The receptacle-moving device comprises device for agitating the test receptacles. In the system, each test receptacle has a bar code affixed to an outer surface.

POLYMERS - Preferred Components: The dispersant is polyalkylene succinic anhydrides; non-nitrogen containing derivative of a polyalkylene succinic anhydride; a basic nitrogen compound selected from succinimide, carboxylic acid amides, hydrocarbyl monoamines, hydrocarbyl polyamines, Mannich bases, phosphonamide, thiophosphonamide and phosphoramidate, thiazole, triazole, copolymers which contain a carboxylate ester with at least one additional polar function, borate post-treated succinimide, and/or ethylene carbonate post-treated succinimide.

BASIC ABSTRACT:

WO 2005068588 A1 UPAB: 20090728

NOVELTY - A lubricant contains a polyhydroxy carboxylic-acid amide (1).

DETAILED DESCRIPTION - A lubricant contains a polyhydroxy carboxylic-acid amide of formula (1).

R1=2-20C alkyl substituted by 2 or more hydroxyl groups;

R2=8-30C hydrocarbon;and

R3=H or 1-30C hydrocarbon.

INDEPENDENT CLAIMS are included for the following:

(1) mixed powder containing a mixture of the lubricant and a metal powder; and

(2) manufacture of sintered compact, which involves compression-molding and sintering the mixed powder.

USE - In mixed powder used in powder metallurgy for manufacturing sintered compacts (all claimed).

ADVANTAGE - The lubricant imparts both flowability and lubricity regardless of whether a complicated pre-treatment step is conducted or not.

TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Property: The lubricant has an average particle diameter of 1-300 microns. Preferred Composition: The lubricant further contains an auxiliary lubricant chosen from metal soap, alkylene bis fatty-acid amide, and fatty-acid amide of formula (2). The lubricant further contains a fatty acid.

R4=7-29C hydrocarbon;and

R5=R3.

The mass ratio of polyhydroxy carboxylic-acid amide and auxiliary lubricant is 30/70-100/0. The mass ratio of the sum total of polyhydroxy carboxylic-acid amide and fatty acid, and

the auxiliary lubricant is 30/70-100/0. The mass ratio of polyhydroxy carboxylic-acid amide

and fatty acid is 20/80-100/0. Preferred Compounds: The fatty-acid amide is hexadecanoic acid (N-octadecenyl) amide or (N-octadecyl) docosenoic acid amide. The fatty acid is 16-22C saturated-fat group monocarboxylic acid.

EXTENSION ABSTRACT:

DEFINITIONS - Preferred Definitions: - R1=5C alkyl substituted by hydroxyl groups;and - R3=H.

SPECIFIC COMPOUNDS - The polyhydroxy carboxylic-acid amide is aldonic acid amide.

EXAMPLE - (N-hexyl) glyceric acid amide was mixed with Atmel 300M (enameled-iron powder) for 30 minutes. The obtained mixed powder had an apparent density of 3.44 g/cm³ as measured by JIS Z 2504, a fluidity of 30.6 second/50 g as measured by JIS Z 2502, a limit-outflow diameter of 35 mm, a compact density of 6.87 g/cm³, and an extract pressure of 15.3 MPa.

WO 2005014763 A1 UPAB: 20090710

NOVELTY - The system has relatively movable contacting surfaces, and surface(s) covered with diamond writer carbon. A lubricating oil containing molybdenum complex and base oil (A), is interposed between contacting surfaces. Oil (A) contains hydrocracking mineral oil(s), wax isomerization mineral oil and poly-alpha-olefinic base oil, and has viscosity of 2-20 mm2/second. Oil contains preset amount of aromatic compound and sulfur.

DETAILED DESCRIPTION - The system has relatively movable contacting surfaces, which are opposed with each other. At least one contacting surface is covered with diamond writer carbon (DLC). A lubricating oil containing a base oil (A), is interposed between contacting surfaces. The base oil (A) contains hydrocracking mineral oil(s), a wax isomerization mineral oil and poly-alpha-olefinic base oil, and has kinetic viscosity of 2-20 mm2/second at 100degreesC. The base oil contains aromatic compound (in mass%) (5 or less) and sulfur (0.005 or less). The lubricating oil further contains sulfur-containing molybdenum complex.

INDEPENDENT CLAIMS are also included for the following:

- (1) lubrication of the system; and
- (2) lubricating oil for system.

USE - E.g. internal combustion engine having contacting surfaces such as piston, piston ring, cylinder bush, connecting rod, crank shaft, bearing, metal gear, chain, belt and oil pump.

ADVANTAGE - The system has favorable low friction characteristics with respect to contacting surfaces, due to lubrication by lubricating oil. TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Oil: The lubricating oil contains metal-type cleaning agent, phosphorus-type anti-wear agent and a friction regulator. The friction

regulator contains 1-40C ester, amine, amide, alcohol, ether, carboxylic acid, ketone, aldehyde and/or carbonate, and oxygen-containing organic compound and/or aliphatic amine. Metal-type cleaning agent contains alkaline earth metal salicylate or perbasic metal-group cleaning agent. Phosphorus-type anti-wear agent contains dithio zinc phosphate.

BASIC ABSTRACT:

WO 2003087178 A1 UPAB: 20080920

NOVELTY - An article of manufacture comprises a copolymer of ethylene and vinyl aromatic monomer having a molecular weight of less than 15000. The copolymer has a backbone having a first terminal group which is methyl and a second terminal group which is vinyl.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for functionalization of a polymer comprising obtaining a copolymer of ethylene and vinyl aromatic monomer having a molecular weight of less than 15000, and effectuating functionalization of the vinyl to make a functionalized copolymer.

USE - The article of manufacture is wax, hot melt adhesive, electrostatic toner or lubricant. The wax is used to formulate paints and coatings, printing inks, carbon paper, photo toners, building an construction material, mold release agent, hot melt adhesive, and candle. The wax may also be used in wood processing, metal working, powder metallurgy and sintering, wax modeling, sizing, and crop protection.

ADVANTAGE - The invention has ethylene styrene copolymer having unique properties and lower molecular weight. TECHNOLOGY FOCUS:

POLYMERS - Preferred Component: The backbone of copolymer is free of vinylidene. The copolymer includes a functional group, preferably halogen, hydroxyl, anhydride, amine, amide, carboxylic acid, ether or nitrile. Preferred Method: The functionalization is chlorination, epoxidation, oxidation, carboxylation or sulfonation. Preferred Composition: The ratio of terminal methyl group to the terminal vinyl group is 0.8:1-1:0.8.

EXTENSION ABSTRACT:

EXAMPLE - A metal precursor solution was 10 mM solution of $Zr(CH_2Ph)_4$, $Hf(CH_2Ph)_4$, $Zr(NMe_2)_4$ or $Hf(NMe_2)_4$ in toluene. The ligand solution was 25 mM solution of the representative ligands in toluene (0.80 mmol) prepared in array of glass vials by dispensing 0.032 ml of 25 mM ligand solution. 0.040 ml Metal precursor solution was added to the vial to form the metal-ligand combination solution. The reaction mixture was heated to 70degreesC for 1 hour, after which time the products were cooled to ambient temperature. 500 mM solution of 1-octene in toluene was added to the ligand-metal composition. An amount of group 13-reagent solution was added to 1 ml vial. This mixture was held at room temperature for 1 minute, during which time 0.420 ml styrene followed immediately by 0.380 ml of toluene, were injected to the reaction vessel. An activator solution was added to the vial. After 30 seconds, a fraction of the total volume of the vial contents was injected in the vessel, followed immediately by approximately 0.7 ml toluene, to bring the total solution volume in the vessel to 5.5 ml. The polymerization and product work-up were then performed.

BASIC ABSTRACT:

WO 2002064713 A1 UPAB: 20050527

NOVELTY - A lubricant concentrate (I) comprising a nitrogen-free alcohol component selected from mono-, di- and trihydroxy compounds and their esters and ethers includes:

- (a) a nitrogen-containing organic compound having at most 14C atoms and at most 8C directly connected C atoms; and/or
- (b) an organic acid having 1-18C atoms.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for:

- (1) a method for maintaining the smooth running of chain conveyors by computer-controlled application of (I) at predetermined positions on the conveyor and periodic application of cleaning agents and/or wash water; and
- (2) a system for maintaining the smooth running of chain conveyors, comprising (I), a cleaning agent, and a lubricating and cleaning apparatus comprising:

- (i) a lubricant tank connected via pumps and pipework to one or more lubricant applicators;
- (ii) a cleaning agent tank connected via pumps and pipework to one or more cleaning agent applicators; and
- (iii) a device for controlling the application cycles and amounts applied.

USE - (I) or (I)-containing solutions are useful for lubricating chain conveyors for transporting plastic, cardboard, metal and glass containers, especially in the food processing industry, especially where the plastic containers are made of polyethylene terephthalate, polyethylene naphthenate, polycarbonate or polyvinyl chloride. TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Components: The alcohol comprises glycerol.

Component (a) is mono-, di- or triethanolamine.

Component (b) comprises acetic acid and/or caproic acid.

The concentrate (I) further comprises an antimicrobial component selected from alcohols, aldehydes, acids, carboxylate esters, amides, phenols, phenol derivatives, diphenyls, diphenylalkanes, urea derivatives, oxygen, nitrogen acetals and formals, benzamides, isothiazolines, phthalimide derivatives, pyridine derivatives, surfactants, guanidines, amphoteric compounds, quinolines, 1,2-dibromo-2,4-dicyanobutane, iodo-2-propynyl butylcarbamate, iodine, iodophores, peroxides and peracids.

EXTENSION ABSTRACT:

EXAMPLE - A typical composition comprised 70% glycerol, 2% triethanolamine, 2% caprylic acid and 26% water.

BASIC ABSTRACT:

WO 2001094504 A2 UPAB: 20091120

NOVELTY - A lubricant composition comprises a lubricant and molybdenum-containing compound(s) in the form of surface-capped nanosized particles.

DETAILED DESCRIPTION - A lubricant composition comprises a lubricant and molybdenum-containing compound(s) in the form of surface-capped nanosized particles of formula (I).

(Z)n(X-R)m (I)

Z = inorganic particles of size 1-100 nm comprising molybdenum and sulfur;

X-R = a surface-capping agent;

X = a functional group capable of specific sorption and/or chemical interaction with the Mo/S particles;

R = 4-20C alkyl or alkylated cycloalkyl;

m, n = numbers such that m:n = 1:1 to 10:1.

An INDEPENDENT CLAIM is also included for the preparation of (I).

USE - The organo molybdenum derivatives are used as multifunctional friction modifier, antiwear, extreme pressure and antioxidant additives in lubricants e.g. in car engine oils.

ADVANTAGE - The nanosized particles have improved solubility and stability in hydrocarbons (or similar solvents). Coagulation is prevented.

TECHNOLOGY FOCUS:

INORGANIC CHEMISTRY - Preferred Inorganic Particles: The Z particles are MoS₃, MoS₂O, Na₂MoS₄, Na₂MoS₃O, (NH₄)₂MoS₄, (NH₄)₂MoS₃O or their hydrates.

ORGANIC CHEMISTRY - Preferred Surface-Capping Agent: The X-R groups are mono-, di- or trialkylamines, (di)carboxylic acids or their amides, alicyclic imides, ammonium or alkali metal dialkyldithiocarbamates, di(or tri)valent metal bis(or tris) dialkyldithiocarbamates, tetraalkyl thiuram disulfides or their derivatives.

Preferred Amines: The amines are of formula (II)

R₁R₂R₃N (II)

R₁, R₂, R₃ = H, 1-20C alkyl, 6-16C alkylaryl or aryl.

Preferred Acids/Amides: The acids or amides are of formula (III).

R₄C(=O)X (III)

X = OH, NH₂, NHR₄ or NR₄R₄; and

R₄ = 1-40C alkyl (optionally partially unsaturated).

Preferred Alicyclic Imide: The alicyclic imide is of formula

(IV).

R₅ = H, C(=O)NHR₇ or alkylene amine;

R₆ = H or 2-400C alkyl; and

R₇ = H or 1-20C alkyl.

Preferred Dialkyldithiocarbamates: The ammonium or alkali metal dialkyldithiocarbamate is of formula (V).

R₈, R₉ = 1-24C alkyl; and

M = Na, K or NH₄.

The divalent metal bis-dialkyldithiocarbamate is of formula

(VI).

M = Fe, Zn, Pb or Cu.

The trivalent metal tris-dialkyldithiocarbamate is of formula

(VII).

M = Sb or Bi.

Preferred Thiuram Disulfide: The tetraalkyl thiuram disulfide is of formula (VIII).

Preferred Composition: The lubricant composition contains 0.2-5 weight% of the Mo compound. It may also contain dispersants, detergents, rust inhibitors, antioxidants, metal deactivators, anti-wear agents, antifoamants, friction modifiers, seal swelling agents, demulsifiers, VI improvers and pour point depressants.

Preparation (claimed): (I) are prepared by:

(A) creating a reversed microemulsion comprising a hydrocarbon-soluble surfactant solution in an organic solvent or solvent mixture and an aqueous solution of a water-soluble Mo(IV) compound;

(B) if necessary, converting the Mo(IV) compound into a thio-derivative by reaction with H₂S;

(C) adding a surfactant that chemically interacts with and/or absorbs on the Mo/S moiety;

(D) removing water and organic solvent(s) from the microemulsion and extracting the Mo/S-containing products in the form of surface-capped nanosize particles, using a suitable organic solvent; and

(E) removing this solvent.

Preferred Preparation: The surfactant is cationic, anionic or nonionic. It is preferably a tetraalkylammonium halide, especially a cetyltrimethylammonium halide dissolved in chloroform:n-alkane (1:1 v/v) in concentration 0.01-0.1 mol/L (the alkane is preferably pentane, hexane, heptane, octane or their isomers or mixtures). The surfactant may be added in step (A) or (B). The aqueous Mo solution has pH at most 8.

EXTENSION ABSTRACT:

EXAMPLE - Cetyltrimethylammonium bromide (CTAB) (0.652 g) was dissolved in chloroform (45 ml) and 100 microliters of a saturated aqueous solution of (NH₄)₆Mo₇O₂₄·2H₂O were added with stirring. The opaque solution was heated and then isooctane (20 ml) and chloroform (20 ml) were added followed by 10 drops of concentrated aqueous HCl. Excess H₂S was bubbled in until a pale yellow solution was obtained. 11 ml of a solution obtained by dissolving isopropyloctadecylamine (0.577 g) in chloroform (50 ml) (Mo:N = 1.5) were added. Three days later, all solvents were evaporated and the residue was stirred with tetrahydrofuran (30 ml), undissolved CTAB containing some MoS₃ was filtered off, and the resulting dark clear solution was evaporated.

BASIC ABSTRACT:

DE 19918199 A1 UPAB: 20050705

NOVELTY - Hydraulic fluids containing 0.01-50 wt% cyclic carboxylic acid derivative(s) in the form of a lactone(s) or lactam(s) with 4-9 atoms in the ring.

DETAILED DESCRIPTION - Hydraulic fluids containing 0.01-50 wt% cyclic carboxylic acid derivative(s) of formula (I).

X = O or NR1;

R1 = H, 1-20C linear or branched alkyl (optionally with up to 9 non-adjacent in-chain oxygen atoms and/or up to 6 hydroxyl group substituents), cycloalkyl or optionally substituted phenyl;

A = -CR2R3-;

R2, R3 = H or 1-8C alkyl (optionally with up to 4 non-adjacent in-chain O atoms and/or up to 3 OH groups); and
n = 2-7.

An INDEPENDENT CLAIM is also included for motor vehicle brake fluid containing 0.01-50 weight% (I).

USE - As hydraulic fluids, especially brake fluids for motor vehicles.

ADVANTAGE - Hydraulic fluids with high equilibrium reflux boiling points (dry and wet) and low viscosities at low temperature (dry or in presence of water), combined with low corrosiveness, good water compatibility, gentle pH, good cold, high-temperature and oxidation stability, good chemical stability, good compatibility with elastomers or rubber and good lubricating properties. TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Composition: Brake fluid as above which also contains 0.1-95 weight% polyglycol ether(s) and/or their borate esters, and/or 0.1-50 weight% polyglycol(s) and/or 0.01-10 weight% corrosion inhibitor(s).

EXTENSION ABSTRACT:

DEFINITIONS - Preferred Definitions: - X = NR1; - R1 = H or 1-6C alkyl (optionally with up to 3 non-adjacent in-chain O atoms and/or up to 2 OH groups); - R2, R3 = H or methyl; and - n = 2, 3 or 4.

EXAMPLE - Brake fluid (BF-1) containing 75 weight% methyltriglycol borate, 22 weight% of a mixture of methyltri-, methyltri- and methyltetra-glycol, less than 3 weight% of a mixture of N,N'-dibutylaminoethanol, 1,1'-iminodipropyl-2-ol, tolutriazole and 3-nitrobenzaldehyde and less than 0.5 weight% Bisphenol A was modified by replacing 5 weight% of the methyltriglycol with 5 weight% methyl-pyrrolidone-2. The modified fluid showed kinematic viscosities at -40 degreesC of 702 (833) cSt (DOT 5 specification; dry) or 1058 (1223) cSt (DOT 5.1 spec.; in presence of 4% water), a wet equilibrium reflux boiling point (ERBP) of 184 (181) degreesC and a dry ERBP or 269 (269) degreesC. Values in brackets are for unmodified BF-1. Corresponding values for a commercial DOT 5.1 brake fluid were 900 cSt, 1265 cSt, 180 degreesC and 262 degreesC.

BASIC ABSTRACT:

WO 2000020539 A1 UPAB: 20050411

NOVELTY - Composition includes organic additive containing at least 5 weight% fluorine and a group that can be adsorbed on a metal surface.

DETAILED DESCRIPTION - Composition comprises:

- (a) a major portion of lubricant base (I); and
- (b) a minor portion of an organic additive (II) grafted with fluorinated olefin.

The additive contains at least one functional group that can be adsorbed on a metal surface and at least 5 weight% fluorine.

An INDEPENDENT CLAIM is also included for an apparatus which comprises:

- (i) a metallic first part;
- (ii) a second part in contact with the first part and moves with respect to one another; and
- (iii) a lubricant containing (I) and (II).

USE - Reduces wear and/or friction between moving parts.

ADVANTAGE - The composition is cost effective and has good lubricant properties.

TECHNOLOGY FOCUS:

ORGANIC CHEMISTRY - Preferred Components: Base (I) is petroleum derived or a synthetic hydrocarbon.

The functional group is carboxylic ester, carboxylic acid, carboxylic amide, imide, amine, phosphoric or phosphonic acid derivative, dithiophosphate ester, ether, hydroxyl or carbonate or thio derivative or heterocyclic, preferably carboxylic ester.

The composition has 500 ppm - 3 weight% fluorine.

INORGANIC CHEMISTRY - Preferred Apparatus: The second part of the apparatus is metal which ferrous metals.

EXTENSION ABSTRACT:

SPECIFIC COMPOUNDS - Eight specific olefinic monomers are claimed: tetrafluoroethylene, chlorotrifluoroethylene, hexafluoropropylene, 3,3,4,4,5,6,6-nonafluoro-1-hexene, perfluoro(methyl vinyl ether), vinylidene fluoride, trifluoroethylene and perfluoro(n-propyl vinyl ether).

EXAMPLE - Perfluoromethyl vinyl ether (60 g) was added to cooled Jayflex-DIDA (RTM: diisodecyl adipate) (80 g) and t-butyl peroxide (7 g). The vessel was heated at 140 degrees C for 5 hour. The contents were removed and then heated in vacuo for 1.5 hours at

140 degrees C. 106 g of the cloudy liquid product was obtained. - The wear scar = 0.435 mm and the coefficient of friction = 0.1345. A standard 150 N neutral oil containing no additives had wear scar = 0.851 mm and coefficient of friction = 0.1424.

BASIC ABSTRACT:

WO 1998011181 A1 UPAB: 20060114

Antioxidant comprises a primary aliphatic hydroxyl linked to an organic backbone such that upon oxidation, a hydroperoxyl moiety capable of boosting the efficacy of free radical scavengers and hydroperoxide decomposer type antioxidants is generated in situ.

Also claimed is a lubricant is prepared from: (a) at least one basestock selected from mineral oils, highly refined mineral oils, alkylated mineral oils, poly alpha olefins, polyalkylene glycols, phosphate esters, silicone oils, diesters and polyol esters and (b) a lubricant additive package comprises the above antioxidant.

USE - For use in lubricants especially crankcase engine oils, two-cycle engine oils, catapult oils, hydraulic fluids, drilling fluids, turbine oils, greases, compressor oils, gear oils and functional fluids.

ADVANTAGE - Has enhanced antioxidant efficiency which can be boosted in situ, thus reducing the rate at which oxidative degradation can occur.

DOCUMENTATION ABSTRACT:

WO9811181

Antioxidant comprises a primary aliphatic hydroxyl linked to an organic backbone such that upon oxidation, a hydroperoxyl moiety capable of boosting the efficacy of free radical scavengers and hydroperoxide decomposer type antioxidants is generated in situ.

Also claimed is a lubricant is prepared from:

(a) at least one basestock selected from mineral oils, highly refined mineral oils, alkylated mineral oils, poly alpha olefins, polyalkylene glycols, phosphate esters, silicone oils, diesters and polyol esters and

(b) a lubricant additive package comprises the above antioxidant.

USE

For use in lubricants especially crankcase engine oils, two-cycle engine oils, catapult oils, hydraulic fluids, drilling fluids, turbine oils, greases, compressor oils, gear oils and functional fluids.

ADVANTAGE

Has enhanced antioxidant efficiency which can be boosted in situ, thus reducing the rate at which oxidative degradation can occur.

EXAMPLE

A polyalpha olefin basestock containing an antioxidant which is derived from 75% 'PAO6' (RTM:1-decene oligomer) and 25% monopentaerythritol/3,5,5-trimethyl hexanoic acid gave HPDSC (high pressure differential scanning calorimetry) decomposition time of 10.86 minutes. This compared with 10.65 minutes for the basestock alone.

PREFERRED COMPOSITION

The antioxidant is the reaction product of (a) an alcohol $R(OH)_n$, where $R = 2-20C$ aliphatic and $n = 2$ or more and (b) $2-20C$ carboxylic acid, the antioxidant having a hydroxyl number of 5-180. The antioxidant is derived from reactants such that the reaction product contains an unconverted $-CH_2OH$ moiety, and is preferably derived from the reaction product of tris(hydroxymethyl)aminomethane and formaldehyde, thus producing 1-aza-3,7-dioxabicyclo(3.3.0)octyl-5-methanol; or from the reaction product of tris(hydroxymethyl)aminomethane and cyclohexanone, thus producing 2,2-pentamethylene-1,3-oxazolidine-4,4-dimethanol; or from the reaction product of tris(hydroxymethyl)aminomethane and a

carboxylic acid, thus producing amides

$R(C=O)NHC(CH_2OH)_3$; or is derived from the reaction product of tris(hydroxymethyl) aminomethane and carboxylic acid, thus producing substituted oxazolines of general formula (I).

The antioxidant is blended with or grafted onto at least one material selected from mineral oils, polyol esters, polyalpha olefins, fuels, oligomers and polymers. The antioxidant is a metal carboxylic acid complex containing titanium, silicon, aluminium, nickel, iron or copper.

The lubricant is crankcase engine oils, two-cycle engine oils, catapult oils, hydraulic fluids, drilling fluids, turbine oils, greases, compressor oils, gear oils and functional fluids.
